2024 International Conference on Intelligent Systems for Cybersecurity (ISCS) | 979-8-3503-7523-7/24/$31.00 ©2024 IEEE | DOI: 10.1109/ISCS61804.2024.10581086

Abstract -- This research uses cutting-edge machine learning techniques to develop predictive models for player performance in the sports of hockey, kabaddi, and cricket. By utilising historical data including runs scored, number of outs, number of wins, and fitness records, the goal is to revolutionise the traditional methods of player evaluation. Our predictive models' fundamental building blocks are machine learning algorithms, such as naïve bayes , and linear regression. The results should provide sports decision-makers with precise information about a player's abilities and suitability for upcoming games. Additionally, an interactive dashboard built with software like Tableau and Power BI will make predictions easy to visualise and share. It aims to improve team performance and decision-making by bridging the gap between data analytics and sports management.

Index Terms: Predictive models, Player performance, Machine learning techniques, Conventional methods, Player assessment, Linear regression, Sports decision-makers, Interactive dashboard, Sports management.

I. Introduction

The capacity to forecast player performance is crucial in the dynamic world of sports. The performance of athletes in a variety of sports is constantly being evaluated and forecasted by coaches, team managers, and sports enthusiasts. Using cutting-edge machine learning techniques, this research explores the area of predictive modelling for player performance in the sports of cricket, kabaddi, and hockey. The need to make educated decisions regarding team composition, strategy development, and player development is what spurs this initiative. This study aims to develop precise predictive models that can offer insights into player capabilities and suitability for upcoming games by utilising historical data encompassing metrics such as runs scored, number of outs, number of wins, and individual fitness records. Our predictive models are built on top machine learning techniques, which includes linear regression, naïve bayes. These algorithms will be developed using a vast dataset gathered from prior games, which will include a wide range of performance indicators unique to each sport. The findings of this study show great promise. Additionally, this model aims to develop an interactive dashboard using software like Tableau and Power BI, enabling the dissemination of predictions to stakeholders and intuitive visualisation. This study's ultimate objective is to close the gap between data analytics and sports management by providing a workable solution that supports decision-makers in the field.

II. Literature Survey

[1] This paper, authored by Ashutosh Kumar Singh, Jitendra Kumar, Harsh Mittal, and Deepak Rikhari, provides insights into cricket. With the advancement of machine learning, predicting cricket match outcomes has become increasingly challenging. Using machine learning and artificial intelligence, they forecast player performance and player selection based on factors like current form, morale, etc. The paper discusses various methods of machine learning model used in this research.

[2] This study, led by Hasan Ulas Yavuz, Caner Acikada, Boran Sekeroglu, Cevdet Tinazci, and Musa Oytun, evaluates models for predicting specific physical attributes of female handball players with the goal of identifying the critical variables influencing these predictions using the model that performs the best. To forecast how well female handball players will performs in various tests, they employed radial-basis function neural networks, decision trees, support vector regression, and linear regression.. Each model underwent training instances and was trained. R2 scores ranging from 0.86 to 0.97 showed the ability of predicting athletic performance in the study's results.

[3] Authors A.G.M. Imam Hossain ,Sakif Yeaser, Amitabha Chakrabarty, Aminul Islam Anik, presented a method of predicting cricket player's performance for the next matches. Their model combines feature selection techniques and algorithms of linear regression and support vector machine. The model forecasts the runs that batters score and runs that bowlers steal using machine learning. Experimental results demonstrate Mahmudullah, the bowler had an accuracy of 75.3% and Tamim, the batsman had 91.5%.

Authorized licensed use limited to: University of Virginia Libraries. Downloaded on March 13,2026 at 20:51:00 UTC from IEEE Xplore. Restrictions apply.

[4] Jiang Hu, Bingkun Ma, Duy Thien An Nguyen, and Nguyen Hoang Nguyen investigate basketball prediction using both traditional techniques for deep learning and machine learning within their paper. Deep learning does not outperform traditional machine learning on their dataset despite its use. The results show that scoring dominates among starting players for every group, as well as consistent with basketball fans' preferred playing style, as shown by both regression and classification analysis.

[5] In this paper, John S. Zelek, David A. Clausi, Pascale Walters, William McNally, and Kanav Vats presented a transformer network for player identification in NHL videos using their jersey numbers. after receiving player frame sequences as input the transformer provides the likelihoods that the jersey numbers appearing within the player frames. Created approximative frame-level labels for the presence of jersey numbers and used them for a weakly-supervised training approach to train more quickly. utilised player shifts to begin the players' skates at a specific game time from the NHL on-the-spot statistics. Player shifts increased the accuracy of player identification by 6%.

[6] Pranjali Singh, Samarth Agrawal, Binayak Parashar, Krishnay Mudgal, and Pratima Singh analyse every team that has competed within the Pro Kabaddi Division over the course of the last seven seasons in-depth in their paper. In addition, the research forecasts tournament outcomes using machine learning algorithms are logistic regression,then k-nearest neighbors, neural network models, kernel radial algorithms. The goal is to create a predictive model that can improve existing prediction methods and open the door to deeper examination of future issues of a similar nature.

[7] Through the use of machine learning algorithms, Abraham Garca-Aliaga, Moisés Marquina, and Sergio Luengo-Sánchez conducted research with the aim of identifying the places that football players occupy on the field as determined by their technical and tactical abilities. These descriptors were calculated using the on-ball event records of OPTA.. They used RIPPER, a machine learning algorithm that discovered a set of rules, to identify the most distinctive factors for each group to comprehend the differences between player positions more thoroughly.

[8] The research involved the development of a module by K.S. Harine, M. Ramalingam, S. Gokul, and L.S. Mythravarshini to assign players to each of the eight IPL teams and evaluate their performance in various matches. The player's bowling and batting stats were assessed independently. The teams were chosen using the Random Forest Classification technique. This method solves problems relating to regression and classification.

[9] A novel model that is tailored to a player's specific playing position during a game is presented in the paper written by S. Manish, Vandana Bhagat, and R.M. Pramila. A player's performance can be predicted using this method based on their assigned position. For greater clarity and insight, various factors related to each playing position are considered, and the models' performances are evaluated.

[10] They have created a team recommendation system in this research paper by Abhishek Swaminathan, Nikki Wagholikar, Swapnali Kurhade, and Shagun Choudhari. This system rates a player's effectiveness according to their various positions, such as batsman, bowler, wicketkeeper, and all-rounder, as well as their specialised abilities, such as fielding and bowling type. For thorough recommendations, the system also considers additional elements like pitch type and weather.

III. Existing System

The current existing system for player performance prediction in cricket, kabaddi, and hockey primarily relies on subjective judgments and historical records. Team managers and coaches often base their player selection decisions on personal experience, intuition, and limited statistical insights. While some basic performance metrics like runs scored or goals scored are considered, the decision-making process lacks a systematic and data-driven approach. Moreover, existing systems typically do not fully harness the potential of advanced analytics and predictive modeling. They may not account for complex interactions between player attributes, team dynamics, and varying match conditions. As a result, the accuracy and consistency of player selection decisions can be suboptimal, leading to missed opportunities and inconsistent team performance. There is a clear need for a more sophisticated and evidence-based approach that integrates historical performance data and advanced predictive models to assist in the selection of players.

IV. Proposed System

The proposed system represents a paradigm shift in the realm of player performance prediction across cricket, kabaddi, and hockey. Grounded in cutting-edge data science and methods for machine learning, this innovative system intends to revolutionize the way teams select and deploy their players. At its core, the system leverages a diverse array of historical performance data, including player statistics, match outcomes, and fitness records, collected meticulously from multiple sources. These data are subjected to rigorous preprocessing, encompassing data cleaning, feature selection, and engineering, ensuring data quality and relevance. The heart of the system lies in the implementation of a sophisticated linear regression model, meticulously tailored to the intricacies of multi-sport data. This model captures intricate relationships between player attributes, match conditions, and performance outcomes, enabling precise predictions. What sets this system apart is its potential to provide actionable insights for team managers and coaches, revolutionizing their decision-making process. It offers a user-friendly, interactive dashboard powered by visualization tools like Tableau or PowerBI, enabling stakeholders to access and interpret predictions

Authorized licensed use limited to: University of Virginia Libraries. Downloaded on March 13,2026 at 20:51:00 UTC from IEEE Xplore. Restrictions apply.

seamlessly. By embracing data-driven decision-making, teams can optimize player selection, resource allocation, and match strategies. This system revolutionizes player selection in cricket, hockey and kabaddi using algorithms and extensive data analysis. Coaches and managers benefit from its user-friendly interface to make informed decisions. Teams gain an edge by identifying top-performing players and improving game outcomes. Continual improvements ensure its relevance and significance in sports management.

VI. Modules Description

Our project consists of several modules to ensure a seamless experience for users that includes,

1. Data Collection
2. Data Preprocessing
3. Algorithm Implementation
4. Dashboard Creation
5. User Feedback and Integration
6. Continuous Improvement and Maintenance

Data Collection --

This module focuses on gathering comprehensive data related to player performances in cricket, kabaddi, and hockey. It includes metrics such as runs scored, number of outs, and fitness records. The data is sourced from diverse and reliable databases, covering various aspects of players' historical performances. The data is collected from ESPN Sports, Pro Kabaddi and some data is manually added. The data can be collaborated with sports analysts and domain experts to define and prioritize key performance indicators (KPIs) relevant to each sport, ensuring that the collected data aligns with the specific need of coaches and analysts.

Data Preprocessing --

In this module, the collected data undergoes preprocessing to ensure quality and relevance. Tasks include data cleaning to handle outliers and missing values, feature selection to identify the most relevant metrics, and feature engineering to create new informative variables. Implemented data imputation strategies such as mean imputation, median imputation, or regression imputation to handle missing values in the dataset, ensuring that valuable information is not lost during analysis. Uses standardization and normalization techniques to scale numerical features to a uniform range, lessening the effect of feature scale variations on algorithm performance.

TABLE I : FEATURES THAT ARE USED IN HOCKEY TO CLASSIFY PLAYERS

Features	Description
Goals scored	This measures a forward's potential for scoring.
Shots on goal	Shows how accurate and willing the forward is to shoot
Average speed	Reflects skating speed.
Successful dribbles	Stick handling and possession skills are measured.
Average distance skated	Endurance and coverage of midfielders.
Faceoff win percentage	Ability to obtain possession
Pass completion rate	Vision and accuracy of player.
Assists per game	Playmaking ability
Blocked shots	Indicates defensive contribution.
Interceptions	Defensive stance and readiness
Body checks	Evaluates aggressiveness and capacity to disorient opponents.
Successful clearances	Shows the ability to clear the defensive zone with the puck.

TABLE II : FEATURES THAT ARE USED IN KABADDI TO CLASSIFY PLAYERS

Features	Description
Player name	Name of the player
Matches played	Total number of matches played
Raids	Total number of raids recorded
Raid points	Raid points awarded
Raid average	Average value of total raids
Super raids	Total number of the super raids
Tackles	Number of tackles as a total
Tackle points	Tackle points awarded
Tackle average	Average value of tackles
Super tackles	Number of total super tackles

TABLE III : FEATURES THAT ARE USED IN CRICKET TO CLASSIFY PLAYERS

Features	Description
Player name	Name of the player
Batting average	Average runs scored per innings
Batting position	The batter's order of play
Strike rate	Total number of runs in hundred balls
Batted innings	Number of innings that are batted taken as a total
Faced balls average	Overall average balls faced by batter in an innings
Innings bowled	Total innings bowled
Economy- bowling	The average of allowed runs in each over
Strike rate-bowling	The average number of balls needed to get a wicket
Wickets	Number of wickets that player has taken

Authorized licensed use limited to: University of Virginia Libraries. Downloaded on March 13,2026 at 20:51:00 UTC from IEEE Xplore. Restrictions apply.

Algorithm Implementation --

This module involves implementing machine learning algorithms for player performance prediction. Here the actual prediction happens where the player are classified and selected efficiently. Experimented with different machine learning algorithms, including linear regression algorithm, naïve bayes algorithm to identify th e most suitable models for player performance prediction across different sports and scenarios. Explored ensemble learning approaches such as bagging, boosting, or stacking are used to combine multiple base models and leverage their collective strength. The detailed explanation of the following algorithms are as follows.

a. Linear Regression

The Linear Model score prediction can benefit from the application of linear regression, a well-liked machine learning technique for forecasting continuous variables. To produce predictions, it creates a linear connection between the goal variable (score) and the input characteristics. During a training procedure, the model discovers the linear equation's coefficients and uses them to predict scores on fresh data.

The formula for linear regression, for multiple and single variables may be expressed in matrix notation as follows:

$$Y=X.\beta+\epsilon \qquad (1)$$

where

- Y is a vector containing the observed values of the dependent variable.
- X is the name of an independent variable matrix.
- ϵ is a vector of error terms;
- The intercept is one of the coefficients in the vector β.

b. Naïve Bayes

A popular probabilistic classification approach for text classification applications is Naive Bayes. Naive Bayes determines the likelihood that a player will fall into a specific category depending on the values of their attributes as taking into account the statistical independence premise between the features. Players are placed in the category with the highest likelihood. Using the conditional independence assumption and the Bayes theorem, Multinomial Naive Bayes calculates conditional probability P(b|a) is given by:

$$P(b|a) = P(a|b)*P(b) / P(a) \qquad (2)$$

where

- Given characteristics a, the posterior probability of class b is displayed by P(b|a).
- Probability of witnessing the characteristics a given class b is shown by P(a|b).
- P(b) indicates prior probability of class that is b.
- Evidence, or likelihood of witnessing feature a, is shown by P(a).

Dashboard Creation --

After the model is trained, this module is dedicated to creating an interactive dashboard. Visualization tools like Power BI and Tableau are used to develop a user-friendly interface that displays the predictions. The dashboard allows end-users, such as team managers and coaches, to easily interpret and utilize the model's insights. Incorporated interactive elements such as sliders, checkboxes, and dropdown menus to enable users to dynamically filter and explore different subsets of the data, enhancing the dashboard's interactivity and usability. Exploring the ability to export functionality to allow users to download relevant data or visualizations from the dashboard in common formats such as CSV or PDF, facilitating further analysis or sharing of insights.

User Feedback and Integration --

Once the predictions are available on the dashboard, this module focuses on gathering user feedback from team managers, coaches, or other stakeholders. This feedback is crucial for refining the system and ensuring it aligns with the practical needs of end-users. Establishing a feedback loop mechanism within the dashboard interface, allowing users to submit feedback directly from the platform on their experience, usability, and suggestions for improvement.

Continuous Improvement and Maintenance --

The model is designed to evolve continuously. This module involves strategies for ongoing data collection to keep the model up-to-date. It also includes plans for refining the model based on new data and insights, ensuring that the system remains accurate and relevant over time. Exploring the transfer learning techniques and domain adaptation strategies to leverage pre-trained models or knowledge from related domains and adapt them to the specific requirements and characteristics of player performance prediction in different sports contexts.

VIII. Conclusion

As a result of our work, player performance in the sports of hockey, kabaddi, and cricket can now be predicted with exceptional success. We have successfully developed models that can accurately estimate player performance based on crucial indicators like runs scored, number of outs, wins, and fitness records. The creation of an interactive dashboard using user-friendly technologies like Tableau and Power BI that are integrated into a secure web portal with user authentication allows teams and coaches to make informed decisions about player selection and plan development. This data-driven strategy has the potential to completely alter how decisions are made in the sports industry in addition to enhancing individual player performance.

IX. Future Scope

Our project is to predict player performance in hockey, kabaddi, and cricket has a bright future. To further improve prediction accuracy, we plan to refine our machine learning models using cutting-edge algorithms and feature engineering. The key focus will be on real-time performance forecasts during live matches, which will give coaches invaluable information for making decisions during play. We also intend to incorporate player health data to expand into injury prevention and prediction. Additionally coming soon are sentiment analysis, wearable technology integration, and customizable dashboards. Our model will have a significant impact on the field of sports analytics because of research contributions.
